Deep Learning

Word embedding

How to represent words in machine learning?

My favorite pet is cat.

- Treat words as discrete atomic symbols, and therefore 'cat' may be represented as '1' and 'pet' as '2.'
- However, this embedding includes no semantics. Tasks learning from this representation causes models hard to train.
- Better solutions?

Word embedding

- Intuition: Modeling relationships between words.
 - Semantics Similarity
 - CBOW (Continuous Bag-of-Words model),
 - Skip-Gram
 - Grammar / Syntax

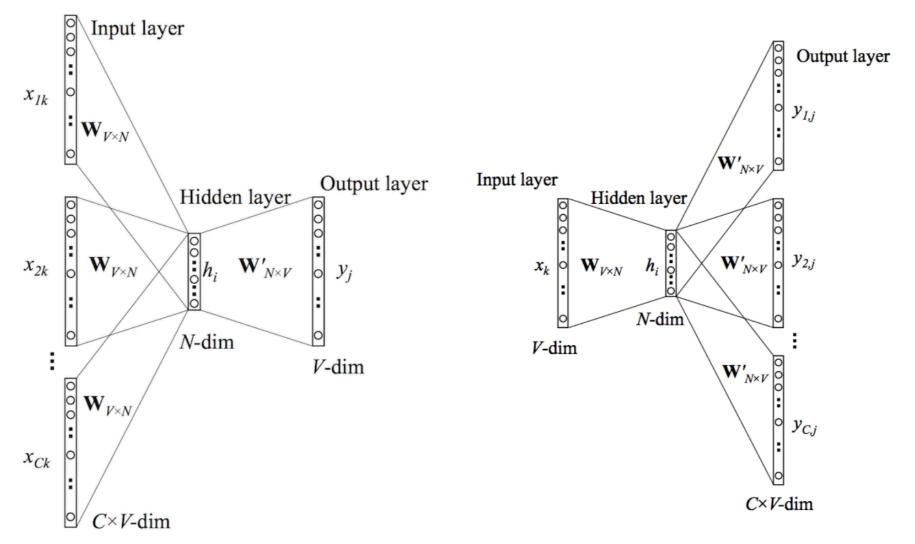

CBOW & Skip-Gram

- Assumptions in CBOW & Skip-Gram:
 - Words with similar meaning / domain have the close contexts.

My favorite pet is ___. cat, dog

CBOW & Skip-Gram

 CBOW: Predicting the target words with context words. Skip-Gram: Predicting context words from the target words.

CBOW & Skip-Gram

• For example, given the sentence:

the quick brown fox jumped over the lazy dog.

CBOW will be trained on the dataset:

```
([the, brown], quick), ([quick, fox], brown), ...
```

Skip-Gram will be trained on the dataset:

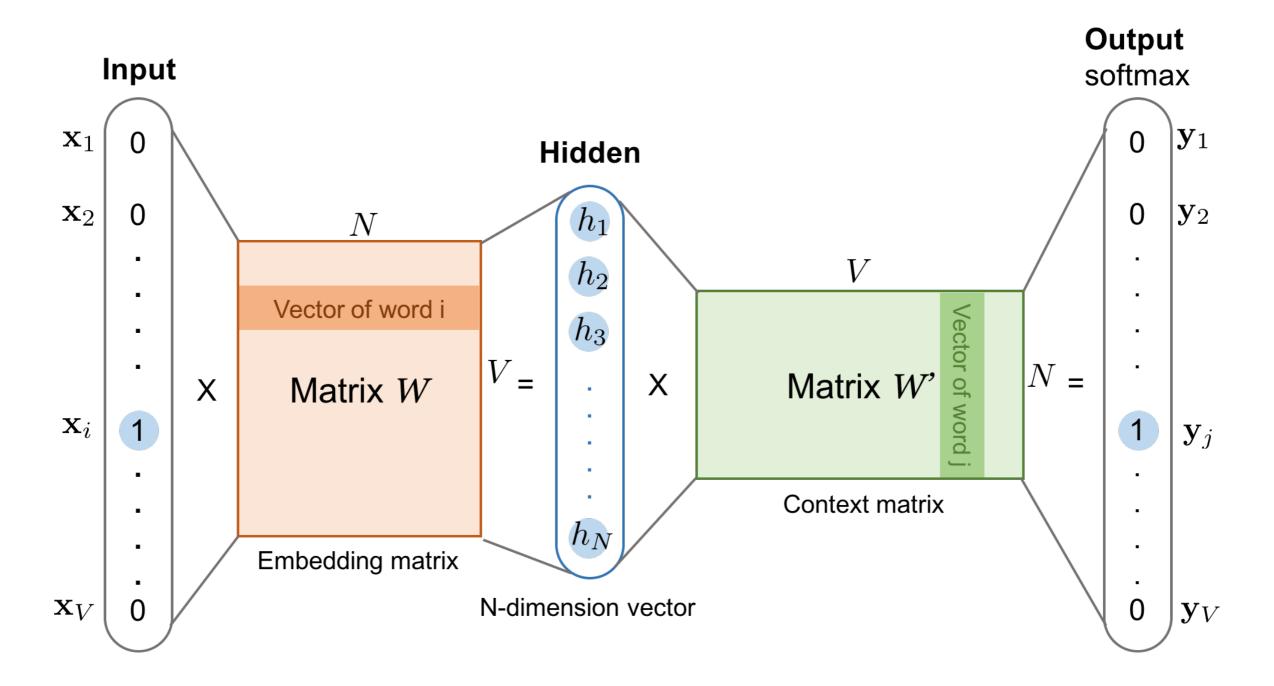

```
(quick, the), (quick, brown), (brown, quick), (brown, fox)...
```

CBOW SkipGram is comparison this is comparison а this а sum visual visual visual visual visual target word

By: Kavita Ganesan

This is a visual comparison

Skip-Gram

Softmax & Words classification

Recap the softmax function:

$$\sigma(\mathbf{z})_i = \frac{e^{z_i}}{\sum_{j=1}^K e^{z_j}}$$

 While training the embedding, we need to sum over the entire vocabulary in the denominator, which is costly.

$$p(w = i \mid \mathbf{x}) = \frac{\exp(h^{\mathsf{T}} v_{w_i'})}{\sum_{j \in V} \exp(h^{\mathsf{T}} v_{w_j'})}$$

|V| (vocabulary size) is thousands of millions

Noise Contrastive Estimation

• Intuition: Estimate the parameters by learning to discriminate between the data w and some artificially generated noise \tilde{w} .

maximum likelihood estimation \rightarrow noise contrastive estimation

Objective function:

$$\arg\max \log p(d = 1 \,|\, w_t \,, x) + \sum_{\tilde{w}_i \sim Q}^{N} \log p(d = 0 \,|\, \tilde{w}_i, x)$$

• Derive form:

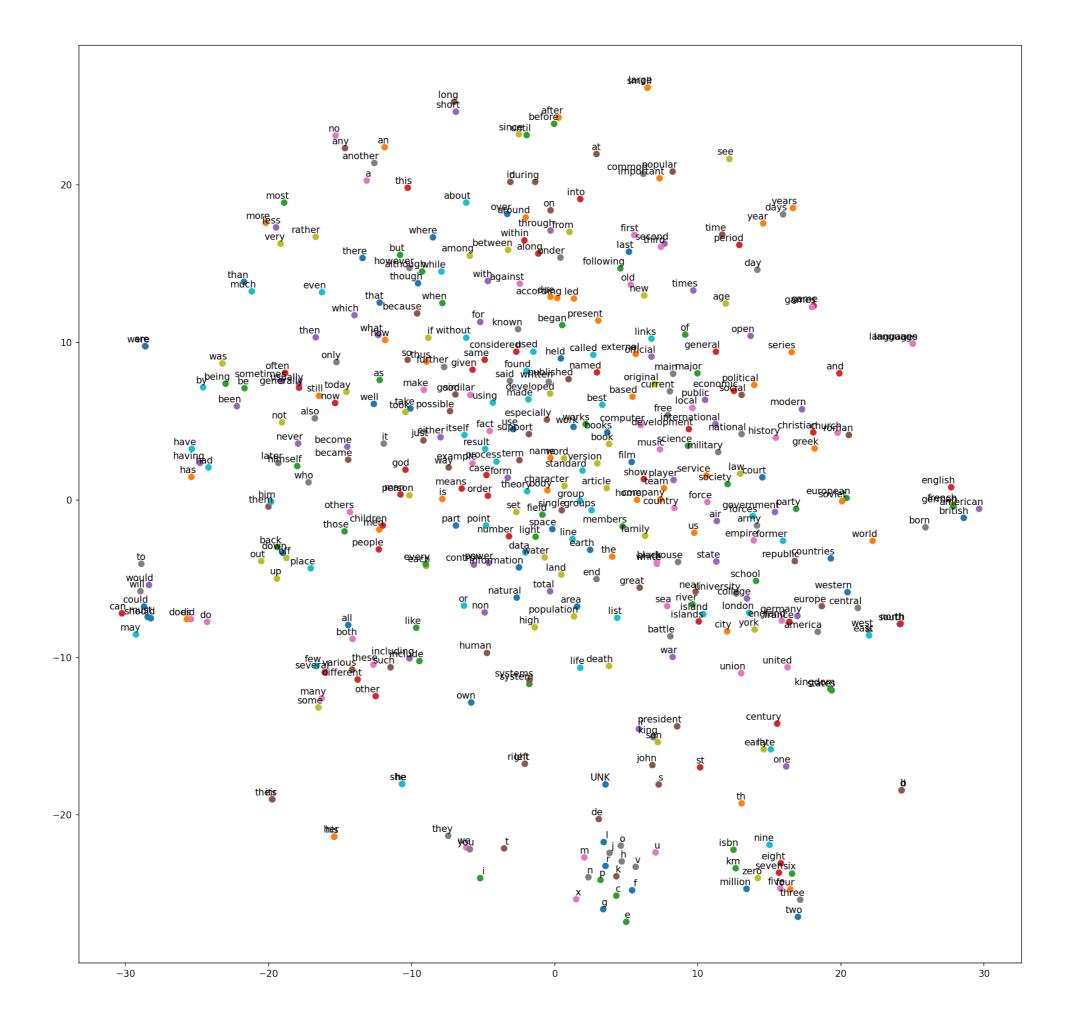

$$\arg\max \log \frac{p(w_t|x)}{p(w_t|x) + Nq(\tilde{w})} + \sum_{\tilde{w}_i \sim Q}^{N} \log \frac{Nq(\tilde{w}_i)}{p(w_t|x) + Nq(\tilde{w}_i)}$$

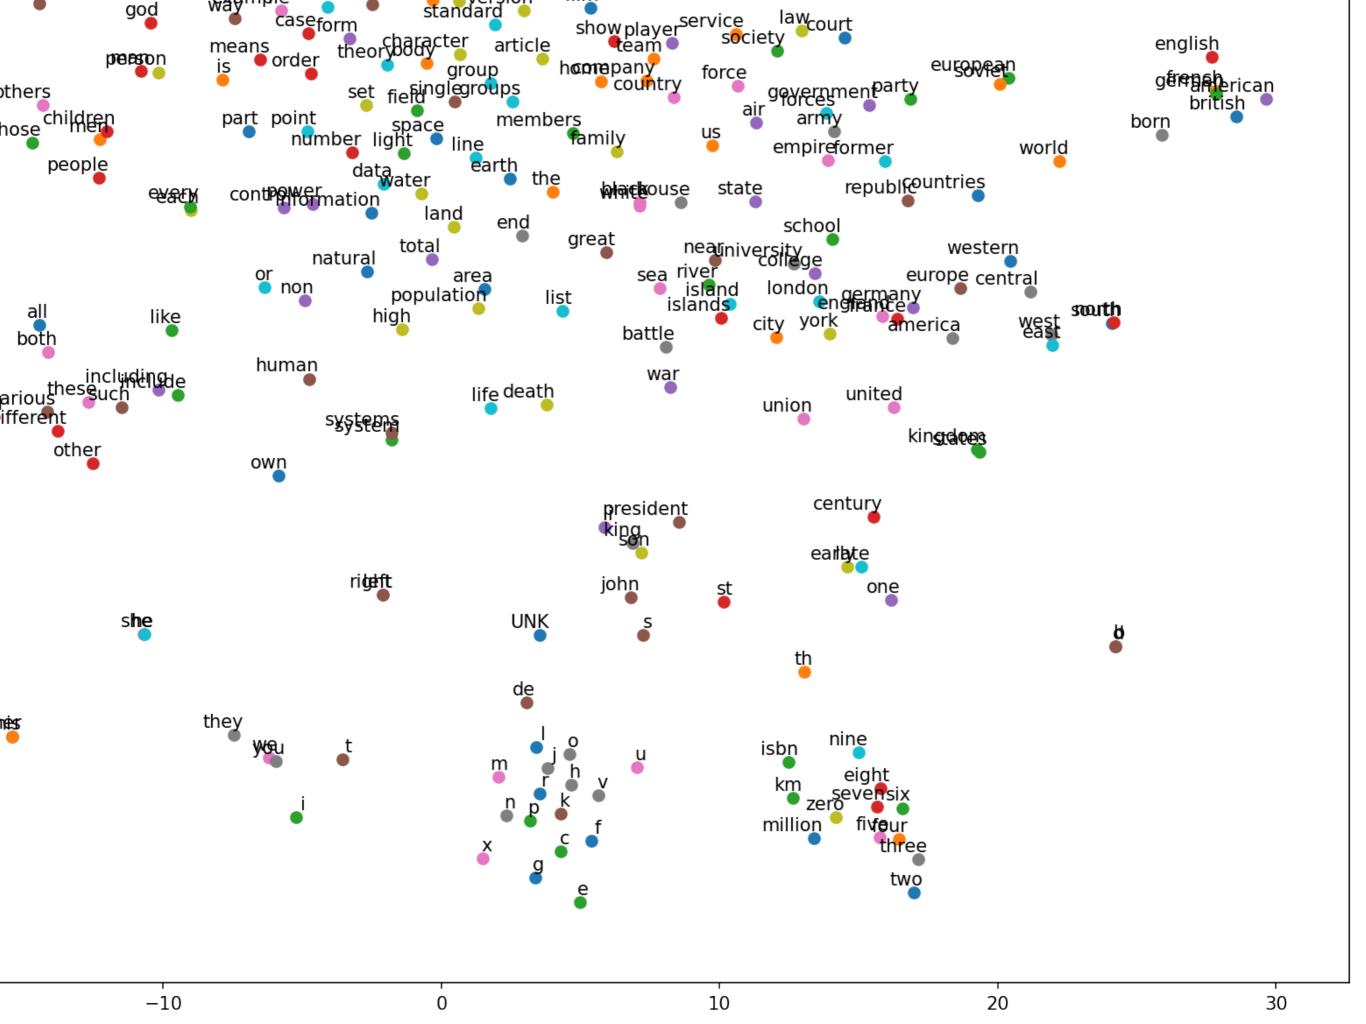

Noise Contrastive Estimation

• Intuition: Estimate the parameters by learning to discriminate between the data w and some artificially generated noise \tilde{w} .

 $maximum\ likelihood\ estimation \rightarrow noise\ contrastive\ estimation$

After training: evaluate with softmax function.

Homework

- Goal: practice model subclassing
 - Train your word2vec via model subclassing
 - Deadline: 2020-11-5(Thur) 23:59

Homework

Functional API:

Homework

Model subclassing:

```
class ResNet(tf.keras.Model):

    def __init__(self):
        super(ResNet, self).__init__()
        self.block_1 = ResNetBlock()
        self.block_2 = ResNetBlock()
        self.global_pool = layers.GlobalAveragePooling2D()
        self.classifier = Dense(num_classes)

def call(self, inputs):
        x = self.block_1(inputs)
        x = self.block_2(x)
        x = self.global_pool(x)
        return self.classifier(x)
```
